

AI Usage Note

Asset Request Bot | Telegram-Based IT Asset Request Automation

1. What AI Helped With

AI was used as a development assistant throughout the project lifecycle. It helped in:

- Designing the project architecture and folder structure.
- Generating Python modules such as `bot.py`, `agent.py`, `validation.py`, and `database.py`.
- Creating the slot-filling conversation flow for collecting asset request details.
- Writing SQLite database operations and HRIS validation logic.
- Generating documentation including README, workflow diagrams, presentation content, and demo scripts.
- Debugging errors related to Telegram bot integration and database operations.

AI significantly reduced development time and helped accelerate prototyping and documentation.

2. What AI Got Wrong

While AI was useful, some outputs required manual review and correction:

- Generated code occasionally contained placeholder values (e.g., Telegram bot token examples).
- Some implementation suggestions did not fully match the project requirements and needed customisation.
- Certain generated workflows were more complex than required and had to be simplified.
- AI-generated code required testing and debugging before production use.

Therefore, all AI-generated outputs were reviewed, modified, and validated manually before implementation.

3. Best Prompt Used

```
>> Create a Telegram-based Asset Request Bot using Python.  
>> The bot should collect asset requirements through slot-filling questions.  
>> Validate employee information using mock HRIS data, generate a structured asset  
request  
and store the request in an SQLite database.
```

This prompt provided the foundation for the project's architecture, conversation flow, validation logic, and database integration.

Declaration: AI was used as a productivity and development aid. Final design decisions, testing, debugging, integration, and project validation were performed by the project team.
